Vision Diff comparison report

BASELINE

Qwen3 VL 2B

CANDIDATE

→ Qwen3 VL 8B

over `chart-read-mini@1.0.0` · 120 samples · re-run #2

IMPROVEMENT

IMPROVEMENT — +0.242 mean score (n=120, 95% CI [+0.150, +0.333])

SCORE DELTA	95% INTERVAL	PAIRED SAMPLES	RESAMPLES
+0.242	[+0.150, +0.333]	120	10,000

The whole confidence interval sits above zero, so the candidate scored higher than the baseline by more than resampling these samples can explain.

Read this first

Reused measurement

The baseline side was a run that had already finished, so the two sides were not measured back to back. Whatever the machine was doing when each ran is baked into its numbers.

Regression matrix

120 samples answered by both models

`Qwen3 VL 2B → Qwen3 VL 8B` · baseline down the rows, candidate across the columns

	Candidate passed	Candidate failed
Baseline passed	**57** Both passed 47.5% of 120	**5** Broke 4.2% of 120
Baseline failed	**34** Fixed 28.3% of 120	**24** Both failed 20.0% of 120

34 fixed against 5 broke, out of 39 disagreements. A split that lopsided arises by chance less than once in a thousand times, so the direction is unlikely to be noise. (exact McNemar, $p < 0.0001$)

Side by side

Every decode parameter is listed, including the ones set to do nothing. An omitted parameter is not a neutral one — it is whatever the local LM Studio defaulted to, which is per-installation and never reported back, so two machines could compute the same fingerprint and decode differently. The bootstrap is seeded from a fixed constant, so re-deriving this interval from the stored predictions gives identical bounds on any machine.

How to read this. The verdict comes from a paired bootstrap confidence interval on the per-sample score difference, not from the gap between two means. Samples both models answered the same way contribute nothing to it, which is the point of pairing. The matrix carries its own test — an exact McNemar over the disagreements — because "how far could the mean have moved" and "is this split more lopsided than a coin" are different questions.

Identical settings do not guarantee identical answers. Temperature 0 buys greedy decoding, not determinism, so a fingerprint identifies the conditions of an experiment rather than promising a repeat of its result. A verdict resting on a delta smaller than a model's own run-to-run variance is not a finding — measure that variance by comparing a model against itself.
